

# AOS: Status Report

Jan 14, 2013

# AOS

- Adaptive Optics System
  - Measures the wavefront error
    - Donut analysis from 8 wavefront sensors.
    - Calculates defocus ( $dz$ ), decenter ( $dx, dy$ ) and tip/tilt ( $x_t, y_t$ )
  - For most of SV only  $dz$  has been under active control (correction sent to hexapod)

# AOS – full active control

- Full active control of all 5 degrees of freedom has had brief tests in the past.
- For several nights in early January, closed loop control on all 5 d.o.f. was enabled.

# 5 nights presented

- For an apples to apples comparison, 5 nights of data with comparable seeing were selected.
  - First two nights Dec 28 and 29 were dz only
  - Next three nights Jan 6, 7 and 8 were full AOS.
- Selected out only period of time each night when east\_commish data was being collected.
  - Small slews, excellent control of all 5 d.o.f.

# dz (focus)

dodz [ $\mu\text{m}$ ]

# dx (decenter)

# dy (decenter)

# xt (tip)

# yt (tilt)

# FWHM (quick reduce)

fwHM

# Ellipticity (quick reduce)

# Conclusion

- $dz$  (focus) controlled to 30 micron rms during small slew surveys.
- $dx$ ,  $dy$ ,  $xt$ ,  $yt$  are all significantly better in mean and rms with control on.
- Best ellipticity (means) were with AOS fully enabled but still small statistics.
- Not dramatic but definitely does not make things worse.
- If we enable full aos now, we can continue to improve, otherwise we lock ourselves into “no control” for a very long time.

# Propose

- Full AOS on by default.
- A simple gui click to disable.
- A simple gui click to (re) enable.

# Details

- Exposures used were all east\_commiss survey
  - Dec 28/29 – 164388 to 164442
  - Dec 29/30 – 164782 to 164839
  - Jan 6/7 – 166255 to 166299
  - Jan 7/8 – 166741 to 166793
  - Jan 8/9 – 167295 to 167371
